WHAT IS CLAIMED IS:

- 1. An electricity meter electrical circuit comprising:
 - a. a plurality of gain stages for amplifying an input signal that is proportional to electricity usage to create a plurality of amplified electricity usage signals;
 - b. an A/D converter for converting the plurality of amplified electricity usage signals into a block of digital samples for each of the plurality of amplified electricity usage signals; and
 - c. a comparison circuit to determine which block of digital samples most accurately represents the input signal.
- 2. The circuit of claim 1 wherein the comparison circuit selects the block of sampled data that has the highest gain stage that is not saturated.
- 3. The circuit of claim 1 wherein the plurality of gains stages comprise a first and second gain stage, wherein the first stage amplifies the signal times two, and the second amplifies the output of the first stage times 4.
- 4. The circuit of claim 1 wherein the plurality of gains stages comprise a first and second gain stage, wherein the first stage amplifies the signal times two, and the second amplifies the output of the first stage times 8.
- 5. The circuit of claim 1 further comprising a voltage bias circuit to lift the input signal voltage into a positive varying input.

TI-35708 9

- 6. An electricity meter electrical circuit comprising:
 - a. a micro-processor/micro-controller;
 - a plurality of gain stages for amplifying an input current signal that is proportional to electricity usage to create a plurality of amplified electricity usage signals;
 - c. an A/D converter for converting the plurality of amplified electricity usage signals into a block of digital samples for each of the plurality of amplified electricity usage signals; and
 - d. a comparison circuit in the micro-processor/micro-controller to determine which block of digital samples most accurately represents the input signal.
- 7. The circuit of claim 6 wherein the comparison circuit selects the block of sampled data that has the highest gain stage that is not saturated.
- 8. The circuit of claim 6 wherein the plurality of gains stages comprise a first and second gain stage, wherein the first stage amplifies the signal times two, and the second amplifies the output of the first stage times 4.
- 9. The circuit of claim 6 wherein the plurality of gains stages comprise a first and second gain stage, wherein the first stage amplifies the signal times two, and the second amplifies the output of the first stage times 8.
- 10. The circuit of claim 6 further comprising a voltage bias circuit to lift the input signal voltage into a positive varying input.

TI-35708 10

- 11. A method for measuring electricity comprising the following steps:
 - a. amplifying an input signal that is proportional to electricity usage to create a
 plurality of amplified electricity usage signals;
 - converting the plurality of amplified electricity usage signals into a block of digital samples for each of the plurality of amplified electricity usage signals;
 and
 - c. comparing the plurality of blocks of digital samples to determine which block most accurately represents the input signal.
- 12. The method of claim 11 wherein the comparison step selects the block of sampled data that has the highest gain block of digital samples that is not saturated
